BACKGROUND OF THE INVENTION

Field of the Invention

The disclosed invention relates to intravascular therapeutic devices and delivery systems therefor, and more particularly, to expandable stents and delivery systems which may be used in the treatment of blood vessel disorders. More specifically, this invention relates to extremely small expandable stents and delivery systems used to treat partially occluded blood vessels, or aneurysms, within the brain.

Description of the Prior Art

On a worldwide basis, nearly one million balloon angioplasties are performed annually to treat vascular diseases such as blood vessels that are clogged or narrowed by a lesion or stenosis. The objective of this procedure is to increase the inner diameter of the partially occluded blood vessel lumen. In an effort to prevent restenosis without requiring surgery, short flexible cylinders or scaffolds, referred to as stents, are often placed into the blood vessel at the site of the stenosis. Stents are typically made of metal or polymers and are widely used for reinforcing diseased blood vessels. Stents are also useful in treating aneurysms by providing an internal lumen to cover an aneurysm and thus reduce the flow of blood and the pressure within the aneurysm.

Some stents are expanded to their proper size using a balloon catheter. Such stents are referred to as "balloon expandable" stents. Other stents, referred to as "self-expanding" stents, are designed to elastically resist compression in a self-expanding manner. Balloon expandable stents and self-expanding stents are compressed into a small diameter cylindrical form and
5 deployed within a blood vessel using a catheter-based delivery system.

Recently, stents have been developed with radiopaque markers to aid in the visualization of the stent upon deployment. Radiopaque markers facilitate the positioning of the stent within a blood vessel by allowing a physician to determine the exact location, size, and orientation of the stent under x-ray or fluoroscopy. These markers are typically formed of a radiopaque material
10 such as tantalum, zirconium, titanium, or platinum. Published U.S. Patent Application No. 2002/0082683 entitled, "Radiopaque Markers For Implantable Prosthesis," discloses one such radiopaque marker comprised of a pigtail, knot, or ring, of tantalum wire wrapped around a crossing point of struts within a stent.

15 SUMMARY OF THE INVENTION

In accordance with one aspect of the present invention, there is provided an expandable stent and delivery system. The delivery system includes an elongated core member having proximal and distal cylindrical members disposed about the distal portion of the elongated core member. The distal cylindrical member is generally positioned distally from the proximal
20 cylindrical member. The proximal and distal cylindrical members are spaced apart to define a gap. The expandable stent is comprised of a small diameter, thin walled, skeletal tubular member. The wall of the tubular member is cut to define a plurality of cells which are formed by a plurality of interconnected strut members. One of the strut members is formed with a threaded

portion on the strut member. A coil comprised of radiopaque material is wound onto the threaded portion of the strut member to thereby define an anchor member which also serves as a radiopaque marker. The anchor member has a longitudinal length slightly shorter than the longitudinal length of the gap. The expandable stent is mounted on at least one of the cylindrical members of the delivery system and is positioned such that the anchor member is interlocked within the gap. The elongated core member and stent are carried by a deployment catheter which compresses the expandable stent about one of the cylindrical members thereby causing the anchor member to be retained in the gap. With this arrangement, the expandable stent is locked onto the elongated core member until such time as the deployment catheter is withdrawn thereby permitting the stent to expand.

In accordance with another aspect of the present invention, the expandable stent includes a plurality of strut members formed with threaded portions on the strut members. A coil comprised of radiopaque material is wound onto the threaded portion of each of the strut members to thereby define anchor members which also serve as radiopaque markers. The anchor members are preferably positioned within the distal and/or proximal section of the expandable stent.

In accordance with still another aspect of the present invention, the expandable stent includes a flared proximal section and a flared distal section with outer diameters of the flared sections being greater than the outer diameter of the central section of the stent. The flared proximal section and flared distal section have outer diameters up to, or approximately equal to, three times the outer diameter of the central section of the stent.

In accordance with yet another aspect of the present invention, the expandable stent includes a strut member with threads cut into an edge of the strut member. Alternatively, the

strut member may include threads which are cut into opposing edges of the strut member. The coil of radiopaque material is then wound onto the opposing threads of the strut member to serve as the anchor member. In addition, the expandable stent may further include multiple such anchor members.

DESCRIPTION OF THE PREFERRED EMBODIMENT

Figure 1 illustrates an expandable stent 10 and delivery system 12. The delivery system 12 includes a deployment catheter 14 which takes the form of an elongated tube having a lumen 16. Preferably, the proximal section 18 of the deployment catheter 14 is formed of a nylon material having a durometer in the range of about 60D to 75D. The proximal section 18 of the deployment catheter 14 is sufficiently flexible to traverse a blood vessel, but is sufficiently rigid so that it can be pushed distally through the blood vessel. The distal section 22 of the deployment catheter 14 is preferably formed of a pellethane material having a durometer of between 25D and 55D.

A winged hub 24 is coupled to the proximal section 18 of the deployment catheter 14. Formed from a polymer material, the winged hub 24 is used to insert the deployment catheter 14 into a blood vessel, such as a blood vessel within the brain of a patient. The delivery system 12 also includes an elongated core member 26 which is formed of wire, preferably nitinol, but may also be formed from other metal alloys or a polymer material. The core member 26 is slideably disposed within the lumen 16 of the deployment catheter 14 and is tapered so that the proximal portion 28 of the core member 26 is of a greater diameter than the distal portion 30 of the core member 26.

The delivery system 12 further includes a proximal cylindrical member 32 disposed about the distal portion 30 of the core member 26. Preferably, the proximal cylindrical member 32 is a helically wound flexible coil made of metal, but may alternatively be formed of a polymer material. An intermediate cylindrical member 34 (shown within the stent) is also disposed about the core member 26 and is generally positioned distally from the proximal cylindrical member

32. The intermediate cylindrical member 34 is spaced apart from the proximal cylindrical member 32 such that the space between the proximal and intermediate cylindrical members 32, 34 forms a first gap 36. The length of the first gap 36 may range from 0.019 inches to 0.19 inches, with a preferred length of 0.040 inches.

5 A distal cylindrical member 38 is disposed about the core member 26 and is generally positioned distally from the intermediate cylindrical member 34. The distal cylindrical member 38 is spaced apart from the intermediate cylindrical member 34 such that the space between the intermediate and distal cylindrical members 34, 38 forms a second gap 40. The length of the second gap 40 may range from about 0.019 inches to 0.19 inches, with a preferred length of 10 0.040 inches. Preferably, the distal cylindrical member 38 is a helically wound flexible coil made from metal, but may alternatively be formed of a polymer material. The delivery system 12 is described in more detail in U.S. Patent Application Serial No. 10/365,282, entitled "Expandable Stent and Delivery System," filed on February 12, 2003 (Attorney Docket No. CRD-5001-US-NP) and assigned to the same assignee as the present patent application.

15 Mounted on the intermediate cylindrical member 34, the expandable stent 10 may take on many different patterns or configurations. Examples of such stents are disclosed in U.S. Patent Applications Serial Nos. 10/163,116 and 10/163,248, both entitled "Intravascular Stent Device," both filed on June 5, 2002 and assigned to the same assignee as the present patent application. Preferably, the stent 10 is coated with an agent, such as heparin or rapamycin, to prevent stenosis 20 or restenosis of the vessel. Examples of such coatings are disclosed in U.S. Patent Nos. 5,288,711; 5,516,781; 5,563,146 and 5,646,160.

 The stent 10 is preferably laser cut from a tubular piece of nitinol to form a skeletal tubular member. The skeletal tubular member has a thin wall, a small diameter, and when cut

forms a plurality of cells which are created by a plurality of interconnected strut members. The nitinol is treated so as to exhibit superelastic properties at body temperature. The stent 10 includes proximal and distal strut members 44, 46 coupled to the proximal and distal sections 48, 50 of the stent 10. Additionally, the stent 10 includes anchor members 11 positioned on the proximal strut members 44 and distal strut members 46 of the stent 10.

Figure 1A illustrates an enlarged view of the expandable stent 10 mounted on the intermediate cylindrical member 34. As the stent 10 is positioned and mounted on the intermediate cylindrical member 34, the anchor members 11 on the proximal strut members 44 align with and are disposed within the first gap 36, formed by the space between proximal cylindrical member 32 and intermediate cylindrical member 34. Similarly, the anchor members 11 on the distal strut members 46 align with and are disposed within the second gap 40, formed by the space between intermediate cylindrical member 34 and distal cylindrical member 38. In this configuration, the stent 10 is locked in place and may be pushed or pulled through the deployment catheter 14 without damaging or deforming the stent 10.

Figure 2 illustrates the delivery system 12 without the expandable stent 10. The delivery system 12 includes an elongated core member 26 disposed within the lumen 16 of a deployment catheter 14. Proximal, intermediate and distal cylindrical members 32, 34 and 38 are disposed about the distal portion 30 of the core member 26. The first gap 36 is defined as the space between the proximal cylindrical member 32 and the intermediate cylindrical member 34. The second gap 40 is defined as the space between the intermediate cylindrical member 34 and the distal cylindrical member 38. In the embodiment shown in this figure, the intermediate cylindrical member 34 is a helically wound flexible coil. Preferably, the flexible coil is made of a metallic material and has a length less than the length of the stent 10. When the stent 10 is

mounted on the intermediate cylindrical member 34, the stent is constrained about the intermediate cylindrical member and thus locked onto the core member 26 by the deployment catheter 14. In this configuration, the stent and delivery system 12 remain sufficiently flexible to traverse tortuous blood vessels within the brain.

5 Figure 3 also shows the delivery system 12 without the expandable stent 10, however, in the embodiment shown in this figure, the intermediate cylindrical member 34 takes the form of a flexible cylindrical sleeve. Preferably, the cylindrical sleeve is made of a polymer material having a smooth outer surface. In this configuration, a stent with a drug coating may be mounted on the cylindrical sleeve and thereby protected from damage caused by friction between the stent
10 and the intermediate cylindrical member 34.

Attached to the ends of the intermediate cylindrical member 34 are reinforcing members 42. The reinforcing members 42 take the form of metallic rings or disks, and alternatively may be made of a polymer material. Preferably, the reinforcing members 42 are made of the same material as the intermediate cylindrical member 34. The reinforcing members 42 provide
15 support to the ends of the intermediate cylindrical member 34 so that the ends resist deformation. Reinforcing members 42 may alternatively be disposed on the ends of the proximal and distal cylindrical members 32, 38.

Figure 4 illustrates the expandable stent 10 and delivery system 12 positioned within a blood vessel 20 within the brain. Initially, the stent 10 is anchored to the core member 26 by
20 mounting the stent on the intermediate cylindrical member 34 and aligning and setting the anchor members 11 within the first and second gaps 36, 40. The core member 26 is then slid into the deployment catheter 14 to thereby hold the stent 10 in its constrained configuration. Then, the

delivery system 12 is inserted into the blood vessel 20 and advanced distally until the stent 10 is aligned with the blockage area 54.

Figure 5 shows the deployment catheter 14 moved proximally, releasing anchor members 11 on the distal strut members 46 from the second gap 40 and allowing the distal section 50 of the expandable stent 10 to begin expanding. During expansion, the distal section 50 of the stent 10 comes in contact with the wall of the blood vessel 20.

As illustrated in Figure 6, the deployment catheter 14 is again moved proximally, releasing the anchor members 11 on the proximal strut members 44 from the first gap 36 and allowing the proximal section 48 of the stent 10 to expand. Once the stent 10 is fully deployed within the blood vessel 20, the core member 26 remains extended through the stent 10 and thus acts as a guide wire, providing a physician with easier access to locations within the blood vessel distal of the stent.

If, during the deployment process, it is determined that the stent 10 should be relocated or realigned, the deployment catheter 14 may be used to resheath the stent 10. With the stent 10 positioned on the core member 26 as described above, if the deployment catheter 14 is not withdrawn beyond the anchor members 11 on the proximal strut members 44, the stent will remain interlocked on the core member 26. In this configuration, the stent 10 may be resheathed. To resheath the stent 10, the deployment catheter 14 is moved distally forcing the stent back onto the intermediate cylindrical member 34, compressing the distal section 50 of the stent, and forcing the anchor members 11 on the distal strut members 46 to become interlocked within the second gap 40. The stent 10 and delivery system 12 may then be withdrawn or repositioned to a different location within the blood vessel 20.

Figure 7 illustrates the expandable stent 10 fully expanded within the blood vessel 20. As shown, the delivery system 12 has been removed from the blood vessel 20. The expanding force of the stent 10 pushes the blockage area 54 radially outward, thereby opening the blood vessel 20 and thus allowing for greater blood flow.

5 Figures 7A and 7B illustrate the threaded portion 15 of a strut member 46/44 and a radiopaque coil 13. The threaded portion 15 is preferably formed by cutting threads into two opposing edges of a strut member 46/44 when the stent is laser cut from a nitinol tubular member. Alternatively, threads may be cut on only one edge of the strut member or a heat-molding technique may be used to form the threaded portion 15 on the strut member 46/44. The
10 radiopaque coil 13, which is formed of a metallic or polymeric material which exhibits the characteristic of being radiopaque, is preferably formed of tantalum or tantalum alloy. The radiopaque coil may also be comprised of gold, gold alloy, platinum, platinum alloy, titanium, zirconium, bromine, iodine, barium, bismuth, or any combination thereof.

 The radiopaque coil 13 is wound onto the threaded portion 15 to thereby form an anchor
15 member 11, as illustrated in Figure 7B. The radiopaque coil 13 is preferably secured to the threaded portion 15 using an adhesive material, such as a UV adhesive which is thermally cured. The anchor member 11 has an outer diameter between 0.002 inches and 0.100 inches, preferably 0.008 inches, and is between .019 inches and 0.190 inches long, preferably 0.040 inches with a length less than the length of the gaps 36, 40. In addition to being used to interlock the stent 10
20 to the core member 26, the anchor member 11 serves as a radiopaque marker for improved visualization during the deployment of the stent within the blood vessel 20. In an alternative embodiment, the threaded portion 15 may be formed such that the teeth of the threaded portion

are spaced apart to provide sufficient room for turns from two interlocked radiopaque coils.

With this spacing, two radiopaque coils may be wound together onto the threaded portion 15.

Figure 8 illustrates the expandable stent 10 and delivery system 12 aligned with an aneurysm 56 within a blood vessel 20 of the brain. From this configuration, the stent 10 may be
5 deployed and used to cover the aneurysm 56.

As shown in Figure 9, in order to deploy the expandable stent 10, the deployment catheter 14 is moved proximally, allowing the anchor members 11 on the distal strut members 46 to exit the second gap 40. The expandable stent 10 is thus allowed to partially deploy and to begin covering the aneurysm 56.

10 Figure 10 illustrates the stent 10 fully deployed within the blood vessel 20 and the delivery system 12 still within the vessel 20. The deployment catheter 14 is moved proximally causing the anchor members 11 on the proximal strut members 44 to exit the first gap 36 thereby allowing the stent 10 to be fully deployed and to cover the aneurysm 56.

Figure 11 illustrates the expandable stent 10 deployed within the blood vessel 20 after the
15 delivery system 12 has been removed from the blood vessel. The stent 10 covers the aneurysm 56.

Figure 12 shows the expandable stent 10 deployed within the blood vessel 20 with a microcatheter 58 inserted into the blood vessel 20, through the wall of the stent 10, and into the aneurysm 56. In this position, embolic agents and medical devices may be delivered into the
20 aneurysm 56.

Figure 13 shows the expandable stent 10 deployed within the blood vessel 20 and covering the aneurysm 56. An embolic coil 60 is placed within the aneurysm 56 and is confined within the aneurysm 56 by the stent 10.

Figure 14 illustrates the expandable stent 10 in more detail. Preferably, the proximal and distal sections 48, 50 of the stent 10 are flared to produce outer diameters at the proximal and distal ends greater than the outer diameter of the central section of the stent. Flaring of the proximal and the distal sections 48, 50 of the stent 10 is incorporated into the stent design so that the stent conforms to the blood vessel 20. The flared ends of the stent 10 press against the wall of the blood vessel to secure the stent to the blood vessel. The flaring of the proximal distal sections 48, 50 of the stent 10 is accomplished by laser-cutting the stent so that the cells in the proximal and distal sections of the stent are of an elongated configuration. Then, the stent 10 is heat-treated with the proximal and distal sections 48, 50 of the stent constrained into the appropriate flared configuration. Preferably, the proximal and distal sections 48, 50 of the stent 10 are flared to produce outer diameters of twice the outer diameter of the central section of the stent 10. The stent 10 is then heat-treated so that it becomes "self-expanding."

As illustrated in Figure 14, the stent 10 preferably includes eight anchor members 11. The anchor members are preferably positioned within the proximal and distal sections 48, 50 of the stent 10. Anchor members 11 may alternatively be positioned within the central section of the stent 10.

Although a preferred embodiment of the present invention has been described, it is to be understood that various modifications may be made by those skilled in the art without departing from the scope of the claims which follow.
